

Atlas Product Sheet

What is Atlas?

Atlas is Aurora Labs' business intelligence platform for teams that query large datasets directly against their data warehouse. Atlas connects to Snowflake, BigQuery, Postgres, and Redshift, builds dashboards from live queries, and delivers scheduled reports by email or Slack. Atlas is designed for analysts who want the performance of a purpose-built query engine without managing infrastructure.

Query engine

Atlas is powered by the Calcite query engine, a distributed SQL engine with a cost-based optimizer and vectorized in-memory execution. Queries are pushed down to the source system wherever possible, so a dashboard over a filtered subset of a large table does not pull the whole table. The engine maintains an in-memory columnar cache that makes warm queries run at p95 under 2 seconds on the reference cluster. Cold queries, which compile a fresh plan, measure at roughly 4 seconds p95; see the platform architecture report for details.

Dashboards and reports

The dashboard builder supports 40+ chart types including bar, line, area, heatmap, funnel, and pivot tables. Dashboards are versioned and every edit is written to the audit log. Scheduled reports deliver a snapshot or a live link to email or Slack on a daily, weekly, or monthly cadence.

Dashboards can be embedded in your own application with the embed SDK, which supports single sign-on and row-level security.

Security and governance

Atlas encrypts data in transit with TLS 1.2+ and at rest with AES-256. Row-level security lets administrators constrain what each user or team can see without duplicating tables. SSO is supported via SAML and OIDC on Standard and Enterprise tiers. The audit log records every query run, dashboard edit, and permission change, and is retained for 12 months on Standard and 36 months on Enterprise.

Pricing

Atlas is priced per user per month. Starter is \$29, Standard is \$49, and Enterprise is \$99 per user per month with annual billing. Monthly billing is available at a 20% surcharge. Nonprofit and education discounts apply. See [product-pricing.csv](#) for the full price list, including bundles that combine Atlas with Beacon and Nimbus.

Getting started

Create a workspace at app.auroralabs.example, connect a data source, and invite users. The free trial includes 14 days of Standard features with a 1 TB query allowance. The REST API is documented in [api-reference.md](#), and the query editor includes a live explain plan and cost estimation. Support is available through the portal during business hours, and 24/7 support is included on Enterprise.

Product SKUs

Each product and tier has a stable SKU used in orders and the billing system. The Atlas analytics platform is SKU ATL-100, with ATL-101 for the Enterprise tier and ATL-102 for Atlas embedded deployments. Beacon is SKU BCN-100, Nimbus is NMB-100, and the combined bundle is BND-300. SKUs appear on invoices and in the API's billing endpoints, and customers should reference the SKU when raising billing questions. SKUs do not change when prices change, so past invoices remain traceable.

Data connectors

Atlas connects natively to Snowflake, BigQuery, Postgres, and Redshift, plus Amazon S3 for data lake queries. Connections are managed centrally: credentials are encrypted at rest and the connection pool handles warehouse session limits automatically. Connector settings include warehouse or dataset selection, connection timeouts, and optional read-only credentials. BigQuery connections can use service-account keys or workload identity, and Snowflake connections support key-pair authentication. The connector framework pushes predicates down to the source so filtered queries never scan the full table.

Embedding and API access

Every Atlas capability is available through the REST API, which is documented in [api-reference.md](#) and covered by official SDKs for Python, TypeScript, and Go. Dashboards can be embedded in your application with the embed SDK, which supports row-level security, SSO, and custom theming. API keys are scoped per capability and rotated on a schedule you control. The audit log records every API call with the key identifier, so unusual usage is attributable to a specific credential.

Admin console

Workspace administrators manage users, teams, data source connections, and billing from the admin console. Role-based access control assigns admin, editor, and viewer roles per team. The console supports SCIM provisioning for user lifecycle management, and session policies enforce login frequency and device requirements. The console also hosts the audit log, export tools, and the data subject request portal described in the privacy policy.

Migration from legacy BI

Teams migrating from legacy business intelligence tools can use the migration assistant, which imports dashboard definitions and saved queries from Tableau, Looker, and Power BI. The assistant maps data source connections, converts chart types to the closest Atlas equivalent, and flags queries that need manual review. Migration runs are staged: review the converted assets in a staging workspace before promoting them, and the audit log keeps a record of the import. Most teams complete a migration in under two weeks.

Performance expectations

Atlas performance depends on the connected warehouse and the query shape. On the reference cluster, warm dashboard queries run at p95 under 2 seconds, and the columnar cache serves repeated queries without contacting the warehouse. Scheduled report generation is capped at 200 reports per hour per workspace on Standard and 1,000 on Enterprise. The performance commitments and the availability guarantee are defined in [sla-agreement.md](#), and measured uptime is published monthly on the [status page](#).
